**ABSTRACT**

All solutions of a generalized minimal partial realization problem are parametrized in an easy way using the basis matrix concept. This basis matrix can be computed in an efficient way and is also used to solve several other interpolation problems. © Elsevier Science Inc., 1997

**1. INTRODUCTION**

This paper is part of a series of papers [13–21] in which a methodology is developed, based on the basis matrix concept, to solve different kinds of interpolation problems: scalar, vector, and matrix rational interpolation problems, Padé, Padé-Hermite, simultaneous Padé approximation, etc. The matrix rational interpolation problem solved here is a generalization of the minimal partial realization problem. The classical minimal partial realization problem plays an important role in linear system theory. Given a sequence of Markov parameters  $M_k \in \mathbf{F}^{p \times q}$ ,  $k = 0, 1, \dots$ , where  $\mathbf{F}$  is an arbitrary field, and some  $\sigma \in \mathbf{N}$ , find all matrix rational functions  $Z$  such that with  $M(z) := \sum_{k=0}^{\infty} M_k z^{-k}$

$$M(z) - Z(z) = O_-(z^\sigma)$$

---

\* E-mail: Marc.VanBarel@cs.kuleuven.ac.be.

such that  $Z$  has minimal McMillan degree. The McMillan degree is a measure for the complexity of the matrix rational function  $Z$ . For discrete-time systems, the Markov parameters are just the values of the impulse response. For more details, we refer the interested reader to the book of Kailath [12].

We generalize this problem in several directions. First, we allow there to be a finite number of  $M_k$  with negative index, so that  $M(z)$  is a formal Laurent series. Second, we allow some shifts, which give “weights” to the degrees of the rows of the polynomial matrices  $N(z)$  and  $D(z)$ , where  $ND^{-1} := Z$  is a right polynomial matrix fraction description of  $Z$ . These shifts will influence the order conditions on the difference  $M - Z$  columnwise. Third, we introduce some rowwise parameters in the order conditions of  $M - Z$ , so that, together with the previous generalization, we actually get componentwise order conditions. Note that, on generalizing the minimal partial realization problem, the interpretation within linear system theory is not clear any more.

The paper is organized as follows. Section 2 introduces the concepts and notation necessary to define the generalized minimal partial realization problem in Section 3. To solve this problem, it is linearized in Section 4 and interpreted as a polynomial vector interpolation problem at  $\infty$  in Section 5. Section 6 gives the algorithm to compute a basis matrix for this problem, allowing one to write down all polynomial vector solutions with limited complexity in an easy way. In [14], the concept of a basis matrix is used to solve the rational interpolation problem. In [18], the algorithm of [14] is generalized to allow confluent interpolation points, poles, and  $\infty$  as an interpolation point. The algorithm of [18] is based on the fact that all solutions of an equivalent linearized interpolation problem can be written in terms of some basis vectors of an  $\mathbf{F}[z]$ -submodule of the module of all polynomial vectors  $\mathbf{F}[z]^n$ . To add a new interpolation condition, we only have to update this set of basis vectors. This can be done in a fast and reliable way, leading to  $O(k^2)$  flops for  $k$  interpolation conditions. For the pole-free problem, this has been generalized to the vector case [4, 9, 15, 16] and also to the matrix case [6, 5, 17]. For the matrix rational interpolation problem with poles as interpolation points, we refer to [13]. Once we have the basis vectors, we can parametrize all solutions of the original rational interpolation problem having minimal complexity [17]. Section 7 applies this idea to the generalized minimal partial realization problem. Two examples are given in Section 8. The  $V$  and  $W$  polynomial matrices of [1] play the roles of basis matrices to solve the *classical* problem. Such basis matrices, or *generating systems*, play an important role in related problems of linear system theory. See, e.g., [2, 3].

Instead of updating the basis matrix when one new interpolation condition is added, one could impose several interpolation conditions at once and compute the new basis matrix in an efficient way [19, 21]. These so-called

“lookahead” procedures can be used to enhance the numerical stability of fast methods to compute Padé approximants and to solve related Hankel systems of linear equations [10]. For Toeplitz systems, we refer the reader to [11]. Generalized Sylvester matrices and related multidimensional Padé systems are handled in [7, 8], while block Toeplitz systems and related interpolation problems are solved in [20].

## 2. NOTATION

We will use the following notation:

$\mathbf{F}$  denotes a field (finite or infinite).

$\mathbf{F}[z]$  is the set of all polynomials with coefficients belonging to the field  $\mathbf{F}$ .

$\mathbf{F}(z^{-1})$  denotes the set of formal Laurent series with only a finite number of terms with positive powers. Similarly for  $\mathbf{F}(z)$ .

$\mathbf{F}^{p \times q}$  is the set of all  $p \times q$  matrices with elements from  $\mathbf{F}$ . If  $q = 1$ , we shall use the notation  $\mathbf{F}^p$  instead of  $\mathbf{F}^{p \times 1}$ . Similarly for  $\mathbf{F}[z]^{p \times q}$  and  $\mathbf{F}(z^{-1})^{p \times q}$ .

If  $A$  is a  $p \times q$  matrix, we denote the element of row  $i$  and column  $j$  of  $A$  using the corresponding small letter, i.e.,  $a_{i,j}$ , and write  $A =: [a_{i,j}]_p^q$  or, if  $p$  and  $q$  are clear from the context,  $A =: [a_{i,j}]$ . If  $\vec{\kappa} \in \mathbf{Z}^p$  with  $\mathbf{Z}$  the set of all integer numbers, we can construct the following diagonal matrix:

$$z^{\vec{\kappa}} := \text{diag}(z^{\kappa_1}, z^{\kappa_2}, \dots, z^{\kappa_p}).$$

**DEFINITION 1** (Projection operators). If  $M \in \mathbf{F}(z^{-1})^{p \times q}$  and  $\Sigma := [\sigma_{i,j}] \in \mathbf{Z}^{p \times q}$ , we define the projection operators  $\pi_{\Sigma}^+$  and  $\pi_{\Sigma}^-$  as follows:

$$\pi_{\Sigma}^+ M := \left[ \pi_{\sigma_{i,j}}^+ m_{i,j} \right]_p^q$$

and

$$\pi_{\Sigma}^- := \left[ \pi_{\sigma_{i,j}}^- m_{i,j} \right]_p^q$$

with

$$\pi_{\sigma}^+ m := z^{\sigma} (\pi^+ (z^{-\sigma} m)),$$

$$\pi_{\sigma}^- m := m - \pi_{\sigma}^+ m,$$

and

$\pi^+ m$ , := the polynomial part of  $m \in \mathbf{F}(z^{-1})$ .

With  $\Sigma_1, \Sigma_2 \in \mathbf{Z}^{p \times q}$ , we use

$$\pi_{\Sigma_1, \Sigma_2} M := \pi_{\Sigma_2}^+ (\pi_{\Sigma_1+1}^- M)$$

to denote part of  $M$ .

DEFINITION 2 (Order). If  $\pi_{\Sigma}^+ M = 0$ , then we write

$$M = O_-(z^{\sigma_{i,j}-1}) \quad \text{or} \quad M = O_-(z^{\Sigma-1}).$$

Similarly, if  $\pi_{\Sigma}^- M = 0$ , we use the following notation:

$$M = O_+(z^{\sigma_{i,j}}) \quad \text{or} \quad M = O_+(z^{\Sigma}).$$

DEFINITION 3 (Coefficients). For  $m \in \mathbf{F}(z^{-1})$ , we define the  $\sigma$ th coefficient of  $m$  as

$$\text{coeff}(m, \sigma) := \pi_{\sigma, \sigma} m.$$

For  $M \in \mathbf{F}(z^{-1})^{p \times q}$  and  $\Sigma \in \mathbf{Z}^{p \times q}$ , we define the  $\Sigma$ th coefficient of  $M$  as

$$\text{coeff}(M, \Sigma) := \pi_{\Sigma, \Sigma} M.$$

DEFINITION 4 (Strict order). We write

$$M = O_+^s(z^{\Sigma}) \quad \Leftrightarrow \quad M = O_+(z^{\Sigma}) \text{ and } \text{coeff}(M, \Sigma) \text{ has full rank.}$$

We write

$$M = O_-^s(z^{\Sigma}) \quad \Leftrightarrow \quad M = O_-(z^{\Sigma}) \text{ and } \text{coeff}(M, \Sigma) \text{ has full rank.}$$

DEFINITION 5 ( $\vec{\kappa}$ -degree,  $\vec{\kappa}$ -column-reduced). Given  $\vec{\kappa} \in \mathbf{Z}^n$ , any nonzero  $\vec{p} \in \mathbf{F}(r^{-1})^n$  can be written as

$$\vec{p}(z) = z^{\vec{\kappa}} O_-^s(z^0) z^{\alpha}.$$

We call  $\alpha$  the  $\vec{\kappa}$ -degree of  $\vec{p}$ . Note that  $\alpha$  can be negative. ( $\vec{\kappa}\text{-deg } \vec{0} := -\infty$ .) The  $\vec{\kappa}$ -degree of  $P \in \mathbf{F}(z^{-1})^{n \times q}$  is defined as the maximum of the degrees of all possible  $m \times m$  determinants taken from the matrix  $z^{-\vec{\kappa}}P$  with  $m := \min\{n, q\}$ .

A matrix  $P \in \mathbf{F}(z^{-1})^{n \times q}$  is called  $\vec{\kappa}$ -column-reduced iff it is of the form

$$P(z) = z^{\vec{\kappa}} O_{-}^s(z^0) z^{\vec{\alpha}}$$

with  $\vec{\alpha} \in \mathbf{Z}^q$ . It is clear that  $\alpha_j, j = 1, 2, \dots, q$ , denotes the  $\vec{\kappa}$ -degree of the  $j$ th column of  $P$ .

LEMMA 6. Given  $\vec{\kappa} \in \mathbf{Z}^n, n \geq q$ , the matrix  $P \in \mathbf{F}(z^{-1})^{n \times q}$  is  $\vec{\kappa}$ -column-reduced iff  $\vec{\kappa}\text{-deg } P = \sum_{j=1}^q \alpha_j =: |\vec{\alpha}|$  with  $\alpha_j$  the  $\vec{\kappa}$ -degree of the  $j$ th column of  $P$ .

DEFINITION 7 ( $\vec{\kappa}$ -McMillan degree of a right-coprime matrix fraction description). Given  $\vec{\kappa} \in \mathbf{Z}^{p+q}$ , take the  $(p+q) \times q$  polynomial matrix

$$z^{-\vec{\kappa}} \begin{bmatrix} N \\ D \end{bmatrix}.$$

The maximum of the degree of all possible  $q \times q$  determinants taken from this matrix is the  $\vec{\kappa}$ -McMillan degree of the right-coprime polynomial matrix fraction description (RCPMFD)  $ND^{-1}$ .

Any matrix rational function  $Z$  can be written as a RCPMFD  $Z = ND^{-1}$ , i.e., with  $N \in \mathbf{F}[z]^{p \times q}, D \in \mathbf{F}[z]^{q \times q}$  with  $\det D \neq 0$ , and  $N$  and  $D$  right coprime. Moreover, all RCPMFDs of  $Z$  can be represented as  $Z = (NU)(DU)^{-1}$  with  $U \in \mathbf{F}[z]^{q \times q}$  unimodular, i.e.,  $\det U \in \mathbf{F} \setminus \{0\}$ . With  $U$  unimodular, the  $\vec{\kappa}$ -degrees of  $[N^T \ D^T]^T$  and  $[(NU)^T \ (DU)^T]^T$  are equal.

DEFINITION 8 ( $\vec{\kappa}$ -McMillan degree of a matrix rational function). Hence, we define the  $\vec{\kappa}$ -McMillan degree of a matrix rational function  $Z$  as the  $\vec{\kappa}$ -McMillan degree of one of its possible RCPMFDs  $ND^{-1}$ , i.e., the  $\vec{\kappa}$ -degree of  $[N^T \ D^T]^T$ .

THEOREM 9. Any matrix  $P \in \mathbf{F}(z^{-1})^{n \times q}$  can be made  $\vec{\kappa}$ -column-reduced by right multiplication with a unimodular matrix  $U$ . Hence, any  $p \times q$  matrix function  $Z$  can be written as  $Z = ND^{-1}$  with

$$P := \begin{bmatrix} N \\ D \end{bmatrix} \in \mathbf{F}[z]^{(p+q) \times q} \text{ } \vec{\kappa}\text{-column-reduced}.$$

In this case, the  $\vec{\kappa}$ -McMillan degree of  $Z$  is equal to  $|\vec{\alpha}|$ , where  $\vec{\alpha}$  contains the  $\vec{\kappa}$ -degrees of the columns of  $P$ .

### 3. GENERALIZED MINIMAL PARTIAL REALIZATION PROBLEM

We generalize the classical minimal partial realization (MPR) problem by introducing the  $\vec{\kappa}$ -McMillan degree and allowing a polynomial part for the given series of Markov parameters. The order conditions can be taken different for each row.

DEFINITION 10 [Generalized minimal partial realization (GMPR)]. Given the formal Laurent series  $M \in \mathbf{F}(z^{-1})^{p \times q}$ , the shift parameters  $\vec{\kappa}_N \in \mathbf{Z}^p$  and  $\vec{\kappa}_D \in \mathbf{Z}^q$ , and a matrix  $\Sigma \in \mathbf{Z}^{p \times q}$  that can be written as

$$\Sigma = [-\lambda_i - \kappa_{D,j}]_p^q = [\sigma_{i,j}]_p^q \quad \text{with } \vec{\gamma} \in \mathbf{Z}^p$$

(the reason for this condition will become clear later), we look for all  $p \times q$  matrix rational functions  $Z$  such that

$$M(z) - Z(z) = O_-(z^\Sigma) \quad (1)$$

and the  $\vec{\kappa}$ -McMillan degree of  $Z$  is minimal with

$$\vec{\kappa} := \begin{bmatrix} \vec{\kappa}_N \\ \vec{\kappa}_D \end{bmatrix}.$$

Note that we get the classical problem by taking  $\vec{\kappa} = \vec{0}$ ,  $M = O_-(z^0)$ , and  $\gamma_i = \gamma$ ,  $i = 1, 2, \dots, p$ . Allowing different values for the  $\gamma_i$ 's leads to rowwise order conditions with  $\Sigma = [\gamma_i]$ . Measuring the complexity of the rational function  $Z$  using the  $\vec{\kappa}$ -McMillan degree instead of the classical McMillan degree of  $Z$  leads to componentwise order conditions with  $\Sigma = [\gamma_i - \kappa_{D,j}]$ . Note that the column dependency of these order conditions is connected to the way the complexity of  $Z$  is measured.

## 4. LINEARIZATION OF THE PROBLEM

By Theorem 9, we can always represent  $Z$  by a  $\vec{\kappa}$ -column-reduced RCPMFD

$$Z = ND^{-1}$$

with  $N \in \mathbf{F}[z]^{p \times q}$ ,  $D \in \mathbf{F}[z]^{q \times q}$ , and

$$P := \begin{bmatrix} N \\ D \end{bmatrix} \quad \vec{\kappa}\text{-column reduced.}$$

By taking this representation, we see that making the  $\vec{\kappa}$ -McMillan degree of  $Z$  minimal is equivalent to taking the  $\vec{\kappa}$ -degree of  $P$  minimal, i.e., the sum of the  $\vec{\kappa}$ -degrees of the columns of  $P$  minimal.

We shall first handle the special case when  $M$  has the form

$$M = O_-(z^{\kappa_{N,i} - \kappa_{D,j} - 1}) \quad (2)$$

and where the order conditions are such that

$$\Sigma \leq [\kappa_{N,i} - \kappa_{D,j} - 1] \quad (\text{elementwise}),$$

i.e.,

$$\gamma_i \geq -\kappa_{N,i} + 1, \quad i = 1, 2, \dots, p.$$

In Section 7, we will handle the general case, dropping this condition on  $M$  and  $\Sigma$ . In the classical case with  $\vec{\kappa} = \vec{0}$ , this reduces to  $M$  being strictly proper and  $\gamma_i \geq 1$ ,  $i = 1, 2, \dots, p$ .

**THEOREM 11.** *If  $M = O_-(z^{\kappa_{N,i} - \kappa_{D,j} - 1})$  and  $\Sigma \leq [\kappa_{N,i} - \kappa_{D,j} - 1]$  (elementwise), any  $\vec{\kappa}$ -column-reduced RCPMFD  $ND^{-1}$  for the solution  $Z$  of the GMPR problem has the form*

$$\begin{bmatrix} N \\ D \end{bmatrix} = \begin{bmatrix} z^{\vec{\kappa}_N} & 0 \\ 0 & z^{\vec{\kappa}_D} \end{bmatrix} \begin{bmatrix} N_h \\ D_h \end{bmatrix} z^{\vec{\alpha}}$$

with  $D_h = O^s(z^0)$  and  $N_h = O_-(z^{-1})$ .

*Proof.* Because  $\Sigma \leq [\kappa_{N,i} - \kappa_{D,j} - 1]$ , the interpolation conditions (1) imply that

$$M - ND^{-1} = O_{-}(z^{\kappa_{N,i} - \kappa_{D,j} - 1})$$

or, multiplying on the right by  $D$ ,

$$N - MD = O_{-}(z^{\kappa_{N,i} - \kappa_{D,j} - 1})D,$$

which can also be written as

$$\begin{bmatrix} I & -M \end{bmatrix} \begin{bmatrix} N \\ D \end{bmatrix} = O_{-}(z^{\kappa_{N,i} - \kappa_{D,j} - 1})D. \quad (3)$$

Because  $ND^{-1} = Z$  is a  $\vec{\kappa}$ -column reduced RCPMFD for  $Z$ , we can write

$$\begin{bmatrix} N \\ D \end{bmatrix} = \begin{bmatrix} z^{\vec{\kappa}_N} & 0 \\ 0 & z^{\vec{\kappa}_D} \end{bmatrix} \begin{bmatrix} N_h \\ D_h \end{bmatrix} z^{\vec{\alpha}}$$

with

$$\begin{bmatrix} N_h \\ D_h \end{bmatrix} = O_{-}^s(z^0).$$

We can rewrite (3) as

$$\begin{bmatrix} I & -M \end{bmatrix} \begin{bmatrix} z^{\vec{\kappa}_N} & 0 \\ 0 & z^{\vec{\kappa}_D} \end{bmatrix} \begin{bmatrix} N_h \\ D_h \end{bmatrix} z^{\vec{\alpha}} = O_{-}(z^{\kappa_{N,i} - \kappa_{D,j} - 1}) z^{\vec{\kappa}_D} D_h z^{\vec{\alpha}},$$

which is equivalent to

$$\begin{bmatrix} z^{\vec{\kappa}_N} & -Mz^{\vec{\kappa}_D} \end{bmatrix} \begin{bmatrix} N_h \\ D_h \end{bmatrix} z^{\vec{\alpha}} = O_{-}(z^{\vec{\kappa}_{N,i} - 1}) D_h z^{\vec{\alpha}}.$$

Multiplying on the left by  $z^{-\vec{\kappa}_N}$  and on the right by  $z^{-\vec{\alpha}}$  gives us the equivalent relation

$$\begin{bmatrix} I & -z^{-\vec{\kappa}_N} M z^{\vec{\kappa}_D} \end{bmatrix} \begin{bmatrix} N_h \\ D_h \end{bmatrix} = O_{-}(z^{-1}) D_h. \quad (4)$$

From (2), we get that  $-z^{-\vec{\kappa}_N} M z^{\vec{\kappa}_D} = O_-(z^{-1})$ . So (4) gives

$$N_h = O_-(z^{-1}) D_h = O_-(z^{-1}).$$

Hence,  $D_h = O_-^s(z^0)$ . ■

The previous theorem shows that if  $M$  has the form

$$M = O_-(z^{\kappa_{N,i} - \kappa_{D,j} - 1})$$

and  $\gamma_i \geq \kappa_{N,i} + 1$ ,  $i = 1, 2, \dots, p$ , we can look for a RCPMFD  $ND^{-1}$  satisfying the interpolation conditions (1) with  $D$  being  $\kappa_D$ -column-reduced. This implies that

$$P := \begin{bmatrix} N \\ D \end{bmatrix}$$

will be  $\vec{\kappa}$ -column-reduced. Minimizing the  $\vec{\kappa}$ -degree of  $P$  is equivalent to minimizing the  $\vec{\kappa}_D$ -degree of  $D$ .

**THEOREM 12.** *If  $D$  is  $\vec{\kappa}_D$ -column-reduced with column degrees  $\vec{\alpha}$ , the original interpolation conditions (1) are equivalent to*

$$N - MD = O_-(z^{-\gamma_i + \alpha_j}).$$

*Proof.* If  $D$  is  $\vec{\kappa}_D$ -column-reduced, it can be written as

$$D = z^{\vec{\kappa}_D} D_h z^{\vec{\alpha}} \quad \text{with} \quad D_h = O_-^s(z^0).$$

Multiplying the original interpolation conditions (1)

$$M - Z = O_-(z^{-\gamma_i - \kappa_{D,j}})$$

on the right by  $D$  gives us

$$\begin{aligned} N - MD &= O_-(z^{-\gamma_i - \kappa_{D,j}}) z^{\vec{\kappa}_D} D_h z^{\vec{\alpha}} \\ &= O_-(z^{-\gamma_i + \alpha_j}). \end{aligned}$$

Because  $D^{-1} = z^{-\vec{\alpha}} D_h^{-1} z^{-\vec{\kappa}_D}$  with  $D_h^{-1} = O_-^s(z^0)$ , we can go all the way back. ■

To solve the GMPRP, we have to look for polynomial vectors  $\vec{p}_j$ ,  $j = 1, 2, \dots, q$  (the columns of  $[N^T \ D^T]^T$ ),

$$\vec{p}_j = \begin{bmatrix} \vec{n}_j \\ \vec{d}_j \end{bmatrix},$$

such that

$$F(z) \vec{p}_j(z) = O_-(z^{-\gamma_i + \alpha_j})$$

with  $\alpha_j := \vec{\kappa}\text{-deg } \vec{p}_j$  and  $F := [I \ -M]$ . We shall solve this interpolation problem at  $\infty$  using a module theoretic framework.

## 5. POLYNOMIAL VECTOR INTERPOLATION PROBLEM AT $\infty$

DEFINITION 13 (Polynomial vector interpolation problem at  $\infty$ ). Take

$$F \in \mathbf{F}(z^{-1})^{p \times n}, \quad \vec{\kappa} \in \mathbf{Z}^n, \quad \vec{\gamma} \in \mathbf{Z}^p.$$

For each  $\beta \in \mathbf{Z}$ , the polynomial vector interpolation problem looks for all polynomial vectors  $\vec{p} \in \mathbf{F}[z]^n$  satisfying the interpolation conditions

$$F\vec{p} = O_-(z^{-\gamma_i + \beta}) \quad (5)$$

with the additional condition that  $\beta \geq \vec{\kappa}\text{-deg } \vec{p}$ .

It turns out that for every  $\vec{p}$  there exists a  $\beta_p$  such that  $\vec{p}$  satisfies (5) for  $\beta \geq \beta_p$ . Hence, the set  $\mathcal{P}$  of all polynomial vectors  $\vec{p}$  satisfying (5) with a corresponding  $\beta_p$  is the complete set of polynomial vectors, i.e.,  $\mathcal{P} = \mathbf{F}[z]^n$ . Note that  $\mathcal{P}$  is an  $\mathbf{F}[z]$ -module which can be generated by  $n$  basis vectors. Because  $\mathcal{P}$  is the complete  $\mathbf{F}[z]$ -module  $\mathbf{F}[z]^n$ , we know that the columns of any unimodular  $n \times n$  matrix form a set of basis vectors. In the sequel, we want to construct a basis matrix (unimodular) with additional information such that it is easy to derive all solution vectors  $\vec{p}$  satisfying (5) for a given  $\beta$  with the additional condition that  $\beta \geq \vec{\kappa}\text{-deg } \vec{p}$ . The additional information we have to keep with every basis vector  $\vec{b}_j$  is an integer number  $\beta_j$ . We use the notation

$$B := \begin{bmatrix} \vec{b}_1 & \vec{b}_2 & \cdots & \vec{b}_n \\ (\beta_1) & (\beta_2) & \cdots & (\beta_n) \end{bmatrix}.$$

In the next section, we shall design an algorithm that computes such a basis matrix  $B$ . We shall show that all polynomial vectors  $\vec{p}$  satisfying (5) with  $\beta \geq \vec{\kappa}\text{-deg } \vec{p}$  can be represented as

$$\vec{p}(z) = \sum_{j=1}^n a_j(z) \vec{b}_j(z) \quad \text{with} \quad \deg a_j \leq \beta - \beta_j, \quad a_j \in \mathbf{F}[z].$$

## 6. ALGORITHM

To compute such a basis, we construct a recursive algorithm. In each step, we increment one of the  $\gamma_i$ , i.e., we add one new interpolation condition. We can always find  $s_i \in \mathbf{Z}$  such that  $F(z) = O_-(z^{s_i - \kappa_i})$ . Then we can start by putting all  $-\gamma_i = s_i$ . The initial basis matrix  $B$  is

$$B := \begin{bmatrix} \vec{e}_1 & \vec{e}_2 & \cdots & \vec{e}_n \\ (\beta_1) & (\beta_2) & \cdots & (\beta_n) \end{bmatrix}$$

with  $\vec{e}_j$  the  $j$ th identity vector and  $\beta_j$  the  $\vec{\kappa}$ -degree of  $\vec{e}_j$ .

Given  $\beta \in \mathbf{Z}$ , any polynomial vector  $\vec{p}$  with  $\beta \geq \vec{\kappa}\text{-deg } \vec{p}$  satisfies (5). Hence, all solutions can be written as

$$\vec{p} = \sum_{i=1}^n a_i \vec{b}_i \quad (\vec{b}_i = \vec{e}_i)$$

with  $\deg a_i \leq \beta - \beta_i$ . Note also that  $\beta_i \geq \vec{\kappa}\text{-deg } \vec{b}_i$ ,  $i = 1, 2, \dots, n$ .

Suppose now that we have a basis matrix  $B$  such that  $\beta_i \geq \vec{\kappa}\text{-deg } \vec{b}_i$  and, for each  $\beta$ , that every  $\vec{p}$  satisfying (5) with  $\beta \geq \vec{\kappa}\text{-deg } \vec{p}$  can be written as

$$\vec{p} = \sum_{i=1}^n a_i \vec{b}_i \quad \text{with} \quad \deg a_i \leq \beta - \beta_i.$$

The interpolation conditions for the basis vectors can be written as

$$FB = z^{-\vec{\gamma}} [R + O_-(z^{-1})] z^{\vec{\beta}} \quad \text{with} \quad R \in \mathbf{F}^{p \times n}. \quad (6)$$

We call  $R$  the residual.

Let us determine which part of  $F$  has to be known to compute the residual of every polynomial vector  $\vec{p}$  having  $\vec{\kappa}$ -degree  $\leq \beta$ . We can write  $\vec{p}$  as  $\vec{p} = z^{\vec{\kappa}} \vec{p}_h z^\beta$  with  $\vec{p}_h = O_-(z^0)$ . The residual  $\vec{r}$  of  $\vec{p}$  is defined by

$$F\vec{p} = z^{-\vec{\gamma}} [\vec{r} + O_-(z^{-1})] z^\beta, \text{ or}$$

$$Fz^{\vec{\kappa}} \vec{p}_h z^\beta = z^{-\vec{\gamma}} [\vec{r} + O_-(z^{-1})] z^\beta, \text{ or}$$

$$(z^{\vec{\gamma}} F z^{\vec{\kappa}}) \vec{p}_h = \vec{r} + O_-(z^{-1}).$$

Hence, to compute the residual  $\vec{r}$ , we only need the polynomial part of  $z^{\vec{\gamma}} F z^{\vec{\kappa}}$ , or, equivalently,  $\pi_{-\gamma_i - \kappa_j}^+ F$  has to be given.

Suppose we want to compute a basis matrix  $B'$  by incrementing  $\gamma_i$ , i.e.,  $\gamma'_j = \gamma_j$ ,  $j \neq i$ , and  $\gamma'_i = \gamma_i + 1$ . There are two possibilities:

*Case 1:*  $r_{i,j} = 0$ ,  $j = 1, 2, \dots, n$ , i.e., all relevant residuals are zero. We can take  $B' = B$  and  $\beta' = \beta$ . It is clear that  $\beta'_i \geq \vec{\kappa}\text{-deg } \vec{b}'_i$ . We can write (6) as

$$FB' = z^{-\vec{\gamma}'} [R' + O_-(z^{-1})] z^{\beta'} \quad \text{with } R' \in \mathbf{F}^{p \times n}.$$

Consider the set

$$\mathcal{P}'_\beta := \left\{ \vec{p} \mid \vec{p} = \sum_{i=1}^n a_i(z) \vec{b}'_i(z), \deg a_i(z) \leq \beta - \beta'_i \right\}$$

and the set

$$\mathcal{J}'_\beta := \left\{ \vec{p} \mid \beta \geq \vec{\kappa}\text{-deg } \vec{p}, \vec{p} \text{ satisfies (5) for } \vec{\gamma}' \text{ instead of } \vec{\gamma} \right\}.$$

We have to prove that  $\mathcal{P}'_\beta \equiv \mathcal{J}'_\beta$ .

Take an element  $\vec{p}$  of  $\mathcal{P}'_\beta$ . Because  $\beta'_i \geq \vec{\kappa}\text{-deg } \vec{b}'_i$ , it is clear that  $\beta \geq \vec{\kappa}\text{-deg } \vec{p}$  and  $\vec{p}$  satisfies (5) for  $\vec{\gamma}'$  instead of  $\vec{\gamma}$ . Hence,  $\vec{p} \in \mathcal{J}'_\beta$ . On the other hand, take  $\vec{p} \in \mathcal{J}'_\beta$ . We know that

$$F\vec{p} = O_-(z^{-\gamma'_i + \beta}) = O_-(z^{-\gamma_i + \beta})$$

with  $\beta \geq \vec{\kappa}\text{-deg } \vec{p}$ . Because

$$\mathcal{J}'_\beta \subset \mathcal{J}_\beta = \mathcal{P}_\beta = \mathcal{P}'_\beta \subset \mathcal{J}'_\beta,$$

we get that

$$\mathcal{J}'_{\beta} = \mathcal{P}'_{\beta} = \mathcal{J}_{\beta} = \mathcal{P}_{\beta}.$$

*Case 2:  $\exists j$  such that  $r_{i,j} \neq 0$ , i.e., not all relevant residuals are zero.*  
Take  $k$  such that

$$\beta_k := \min\{\beta_j \mid r_{i,j} \neq 0, j = 1, 2, \dots, n\}.$$

We compute the new basis matrix  $B'$  as

$$B' = BV$$

with (only the nonzero elements are displayed)

$$V := \begin{bmatrix} 1 & & & & & & & & \\ & 1 & & & & & & & \\ & & \ddots & & & & & & \\ & & & \ddots & & & & & \\ & & & & 1 & & & & \\ v_1 & v_2 & \cdots & v_{k-1} & v_k & v_{k+1} & \cdots & v_n \\ & & & & & 1 & & & \\ & & & & & & \ddots & & \\ & & & & & & & \ddots & \\ & & & & & & & & 1 \end{bmatrix}$$

with

$$v_j := -\frac{r_{i,j}}{r_{i,k}} z^{\beta_j - \beta_k}.$$

We compute  $\vec{\beta}'$  as  $\vec{\beta}' = \vec{\beta} + \vec{e}_k$ .

It is clear that  $\beta'_j \geq \bar{\kappa} \deg b_j$ ,  $j = 1, 2, \dots, n$ .

Note that  $B'$  is also unimodular because  $B$  and  $V$  are unimodular. Because every column of  $B'$  satisfies the interpolation conditions, i.e.,

$$FB' = O_-(z^{-\gamma'_i + \beta'_j}),$$

we get that

$$FB'\vec{a} = O_-(z^{-\gamma'_i + \beta})$$

with  $\vec{a} = [a_1, a_2, \dots, a_n]^T$  and  $\deg a_i \leq \beta - \beta'_i$ . Because

$$B' = z^{\vec{\kappa}} B_h z^{\vec{\beta}'}$$

with

$$B_h = O_-(z^0),$$

we get that

$$\begin{aligned} B' \vec{a} &= z^{\vec{\kappa}} B_h z^{\vec{\beta}'} z^{-\beta'} z^{\beta} \vec{a}_h \quad \text{with} \quad \vec{a}_h = O_-(z^0) \\ &= z^{\vec{\kappa}} B_h \vec{a}_h z^{\beta}, \end{aligned}$$

so that  $\beta$  is at least the  $\vec{\kappa}$ -degree of  $\vec{p} = B' \vec{a}$ . Hence, every element  $\vec{p}$  of  $\mathcal{P}'_\beta$  is also an element of  $\mathcal{S}'_\beta$ , i.e.,  $\mathcal{P}'_\beta \subset \mathcal{S}'_\beta$ .

To prove that  $\mathcal{P}'_\beta = \mathcal{S}'_\beta$ , we consider the equivalent linear algebra problem and look at the dimension of the solution spaces. We assume that  $\mathcal{P}_\beta = \mathcal{S}_\beta$  and prove that  $\mathcal{P}'_\beta = \mathcal{S}'_\beta$ .

Consider the set  $\mathcal{S}_\beta$ . Using, e.g., the classical basis  $1, z, z^2, \dots$ , we can represent any  $\vec{p}$  having  $\vec{\kappa}$ -degree  $\leq \beta$  by using  $\sum_{i=1}^n \max\{0, \kappa_i + \beta + 1\}$  coordinates. The interpolation conditions (5) can be transformed into a set of linear equations with the coordinates as unknowns. Because  $\mathcal{S}_\beta = \mathcal{P}_\beta$ , we know that the dimension of the solution set is given by

$$\sum_{i=1}^n \max\{\beta - \beta_i + 1, 0\},$$

and a basis is given by the coordinate representation of all polynomial vectors of the form  $z^\delta \vec{b}_i$  with  $0 \leq \delta \leq \beta - \beta_i$ .

Indeed, these vectors are  $\mathbf{F}$ -linearly independent. Suppose they were not. Then there would exist a nonzero constant vector  $\vec{a}$  such that

$$\left[ \vec{b}_1, z\vec{b}_1, \dots, z^{\beta-\beta_1}\vec{b}_1 \mid \dots \mid \vec{b}_n, z\vec{b}_n, \dots, z^{\beta-\beta_n}\vec{b}_n \right] \vec{a} = \vec{0},$$

or, equivalently,

$$B\vec{a}(z) = \vec{0} \quad \text{or} \quad \vec{a}(z) = B^{-1}\vec{0} = \vec{0}, \quad \text{or} \quad \vec{a}(z) = \vec{0},$$

which contradicts our assumption that  $\vec{a} \neq \vec{0}$ .

Incrementing  $\gamma_i$  is equivalent to adding one new linear equation. Therefore, the dimension of the solution space for a fixed  $\beta$  is decreased by one iff the new linear equation is linearly independent of the previous equations.

We have that  $\mathcal{P}'_\beta = \mathcal{J}'_\beta = \mathcal{P}_\beta = \mathcal{J}_\beta$  for  $\beta < \beta_k$ .

For  $\beta \geq \beta_k$ , we know that  $\dim \mathcal{J}'_\beta = \dim \mathcal{J}_\beta - 1$ . We have already shown that  $\mathcal{P}'_\beta \subset \mathcal{J}'_\beta$ , but written in terms of coordinates this means  $\dim \mathcal{P}'_\beta = \dim \mathcal{P}_\beta - 1$ . Therefore,  $\mathcal{P}'_\beta = \mathcal{J}'_\beta$ .

Let us summarize the algorithm.

ALGORITHM 6.1. Given  $F \in \mathbf{F}(z^{-1})^{p \times n}$ ,  $\vec{\kappa} \in \mathbf{Z}^n$ ,  $\vec{\gamma}^* \in \mathbf{Z}^p$ .

**Initialization:**

Choose  $s_i \geq -\gamma_i^*$ ,  $i = 1, 2, \dots, n$  such that  $F = O_-(z^{s_i - \kappa_i})$ .

$B \leftarrow I_n$  ( $n \times n$  identity matrix).

$\vec{B} \leftarrow -\vec{\kappa}$  (the  $\vec{\kappa}$ -degrees of the columns of  $B$ ).

$-\vec{\gamma} \leftarrow \vec{s}$

**While**  $\vec{\gamma} \neq \vec{\gamma}^*$  (not all interpolation conditions are handled):

1. Choose  $i$  such that  $\gamma_i + 1 \leq \gamma_i^*$ ,  $\gamma_i \leftarrow \gamma_i + 1$ .
2. Get the residuals  $r_{i,j}$ ,  $j = 1, 2, \dots, n$ , i.e., the  $i$ th row of  $R$  defined by (6).
3. **If**  $\exists j: r_{i,j} \neq 0$  **then**
  - 3.1. Compute  $k$  such that

$$\beta_k = \min\{\beta_j \mid r_{i,j} \neq 0\}.$$

- 3.2. Construct the unimodular matrix  $V$ , i.e., the identity matrix  $I_n$  except for the  $k$ th row, which has elements

$$v_j = -\frac{r_{i,j}}{r_{i,k}} z^{\beta_j - \beta_k}.$$

- 3.3.  $B \leftarrow BV$ .

- 3.4.  $\vec{\beta} \leftarrow \vec{\beta} + \vec{e}_k$ .

The above algorithm generates a basis matrix  $B$  with additional information  $\beta$  such that it is easy to represent all elements of set  $\mathcal{J}_\beta$  as elements of  $\mathcal{P}_\beta$ .

Note that the algorithm requires  $O(\|\vec{s} + \vec{\gamma}^*\|^2)$  flops. Algorithm 6.1 could be considered a Levinson-type algorithm in the sense that only the first part of the residual series is computed, the part which is needed to continue the computations. On the other hand, one could also consider a Schur-type

algorithm in which the complete residual series is adapted in each step. The residuals, needed to continue the computations, can be read off directly as part of the residual series.

## 7. SOLUTION OF THE GMPR PROBLEM

Let us look at how we can use the algorithm of the previous section to solve the GMPR problem. We look for a numerator column  $\vec{n}$  and corresponding denominator column  $\vec{d}$  such that

$$\begin{bmatrix} I & -M \end{bmatrix} \begin{bmatrix} \vec{n} \\ \vec{d} \end{bmatrix} = O_-(z^{-\gamma_i + \alpha})$$

with

$$\alpha = \vec{\kappa}\text{-deg} \begin{bmatrix} \vec{n} \\ \vec{d} \end{bmatrix}.$$

Rewriting this in terms of the previous algorithm, we get

$$F = \begin{bmatrix} I & -M \end{bmatrix} \in \mathbf{F}(z^{-1})^{p \times n} \quad \text{with} \quad n = p + q.$$

To initialize, we have to find  $\vec{s}$  that

$$F = O_-(z^{s_i - \kappa_j}).$$

### *Special Case*

Remember that we assumed  $M$  to be of the form

$$M = O_-(z^{\kappa_{N,i} - \kappa_{D,j} - 1}).$$

Hence,

$$\begin{aligned} F &= \begin{bmatrix} I & -M \end{bmatrix} = z^{\vec{\kappa}_N} \begin{bmatrix} I & -z^{\vec{\kappa}_N} M z^{\vec{\kappa}_D} \end{bmatrix} \begin{bmatrix} z^{-\vec{\kappa}_N} & 0 \\ 0 & z^{-\vec{\kappa}_D} \end{bmatrix} \\ &= z^{\vec{\kappa}_N} \left[ O_-^s(z^0) \right] z^{-\vec{\kappa}} \\ &= O_-^s(z^{\kappa_{N,i} - \kappa_j}) \\ &= O_-(z^{\kappa_{N,i} - \kappa_j}). \end{aligned}$$

Therefore, we can start the algorithm by choosing

$$\vec{s} = \vec{\kappa}_N > \vec{\gamma} \quad (\text{elementwise}).$$

To get a solution of smallest  $\vec{\kappa}$ -McMillan degree, we take, among all basis vectors for which  $\beta_{i(j)} = \vec{\kappa}\text{-deg } b_{i(j)}$ ,  $q$  basis vectors  $\vec{b}_{i(j)}$ ,  $j = 1, 2, \dots, q$ , having smallest  $\alpha_j := \beta_{i(j)}$ .

Because  $\alpha_j = \vec{\kappa}\text{-deg } b_{i(j)}$ , we know that the  $q \times q$  matrix  $D$  of

$$\begin{bmatrix} N \\ D \end{bmatrix} := \begin{bmatrix} \vec{b}_{i(1)}, \vec{b}_{i(2)}, \dots, \vec{b}_{i(q)} \end{bmatrix}$$

is  $\vec{\kappa}_D$ -column-reduced. Hence,

$$M - Z = O_-(z^{-\gamma_i - \kappa_{D,j}}).$$

In analogy to the classical MPR problem, we get the following result.

**THEOREM 14.** *All solutions of the GMPR problem can be represented as follows. The set of basis vectors generated by Algorithm 6.1 is divided into two subsets:  $B_1 := [\vec{b}_{i(1)}, \vec{b}_{i(2)}, \dots, \vec{b}_{i(q)}]$ , where  $\vec{b}_{i(j)}$ ,  $j = 1, 2, \dots, q$ , are  $q$  basis vectors having smallest  $\alpha_j$  with  $\alpha_j := \beta_{i(j)} = \vec{\kappa}\text{-deg } \vec{b}_{i(j)}$ ; and the remaining basis vectors,  $B_2 := [\vec{b}'_1, \vec{b}'_2, \dots, \vec{b}'_p]$ .*

*We construct two polynomial matrices  $N \in \mathbf{F}[z]^{p \times q}$  and  $D \in \mathbf{F}[z]^{q \times q}$  such that*

$$\begin{bmatrix} N \\ D \end{bmatrix} := B_1 + B_2 \Lambda \quad \text{with } \Lambda \in \mathbf{F}[z]^{p \times q}.$$

*The polynomial matrix  $\Lambda$  contains the parameters with the condition that  $\deg \lambda_{i,j} \leq \alpha_j - \beta'_i$  ( $\beta'_i := \beta$  connected with  $\vec{b}'_i$ ). For a different  $\Lambda$ ,  $Z = ND^{-1}$  will be a different matrix rational function solving the GMPR problem.*

#### General Case

When the constraint  $M = O_-(z^{\kappa_{N,i} - \kappa_{D,j} - 1})$  or  $\Sigma \leq [\kappa_{N,i} - \kappa_{D,j} - 1]$  (elementwise) is not satisfied, we split up  $M$  into a “polynomial part”  $M^+$  and a “strictly proper part”  $M^-$ :

$$M = M^+ + M^-$$

with  $M^+ := \pi_{\kappa_{N,i} \vec{\gamma} - \kappa_{D,j}}^+ M$  and  $M^- := \pi_{\kappa_{N,i} - \kappa_{D,j}}^- M$ . Note that for the classical case, i.e.,  $\vec{\kappa}_N = \vec{0}$  and  $\vec{\kappa}_D = \vec{0}$ ,  $M^+$  and  $M^-$  are the polynomial and the strictly proper part of  $M$  respectively.

Any  $p \times q$  matrix rational function  $Z$  can be split up in a similar way, i.e.,  $Z = Z^+ + Z^-$  with

$$Z^+ := \pi_{\kappa_{N,i} - \kappa_{D,j}}^+ Z \quad \text{and} \quad Z^- := \pi_{\kappa_{N,i} - \kappa_{D,j}}^- Z.$$

Because  $Z^-$  is also rational and satisfies

$$Z^- = O_-(z^{\kappa_{N,i} - \kappa_{D,j} - 1}),$$

we can represent  $Z^-$  using a  $\vec{\kappa}$ -column-reduced RCPMFD

$$Z^- = ND^{-1}$$

with  $D$   $\vec{\kappa}_D$ -column-reduced.

The  $\vec{\kappa}$ -McMillan degree of  $Z$  is equal to the  $\vec{\kappa}$ -degree of

$$\begin{bmatrix} Z^+D + N \\ D \end{bmatrix} \quad (7)$$

if  $(Z^+D + N)D^{-1}$  is a RCPMFD for  $Z$ .

LEMMA 15. *If*

$$\kappa_{N,i} \geq \kappa_{D,j}, \quad i = 1, 2, \dots, p \quad \text{and} \quad j = 1, 2, \dots, q, \quad (8)$$

*then (7) is a RCPMFD for  $Z$ .*

*Proof.* Because  $ND^{-1}$  is a RCPMFD for  $Z^-$ , we know that  $N$  and  $D$  are polynomial matrices. Using (8),  $Z^+$  turns out to be polynomial, and hence  $Z^+D + N$  is also polynomial.

Now, we have to show that  $Z^+D + N$  and  $D$  are right coprime, i.e.,

$$\begin{bmatrix} Z^+D + N \\ D \end{bmatrix}$$

has full rank for all possible values of  $z$ . Suppose that there exists a right common divisor  $R$  of  $Z^+D + N$  and  $D$ , i.e.,

$$Z^+D + N = PR$$

and

$$D = D'R$$

with  $P$  and  $D'$  polynomial matrices. It follows that

$$(Z^+D + N)R^{-1} = Z^+DR^{-1} + NR^{-1} = Z^+D' + NR^{-1} = P$$

is polynomial. Because  $Z^+D'$  is also polynomial,  $NR^{-1}$  is polynomial, so that  $R$  is also a right common divisor of  $N$ . Hence,  $N$  and  $D$  are not right coprime, which contradicts our assumption. ■

Let us look in more detail at the  $\vec{\kappa}$ -degree of (7), which is equal to the  $\vec{0}$ -degree of

$$\begin{aligned} & \begin{bmatrix} z^{-\vec{\kappa}_N} & 0 \\ 0 & z^{-\vec{\kappa}_D} \end{bmatrix} \begin{bmatrix} Z^+ + ND^{-1} \\ I \end{bmatrix} D \\ &= \begin{bmatrix} z^{-\vec{\kappa}_N} Z^+ z^{\vec{\kappa}_D} + z^{-\vec{\kappa}_N} ND^{-1} z^{\vec{\kappa}_D} \\ I \end{bmatrix} z^{-\vec{\kappa}_D} D \\ &= \begin{bmatrix} P^+ + P^- \\ I \end{bmatrix} z^{-\vec{\kappa}_D} D \end{aligned} \quad (9)$$

with

$$P^+ = z^{-\vec{\kappa}_N} Z^+ z^{\vec{\kappa}_D} = O_+(z^0)$$

and

$$P^- = z^{-\vec{\kappa}_N} ND^{-1} z^{\vec{\kappa}_D} = O_-(z^{-1}).$$

Hence, the  $\vec{\kappa}$ -McMillan degree of  $Z$  is equal to the  $\vec{0}$ -degree of

$$\begin{bmatrix} P^+ + P^- \\ I \end{bmatrix}$$

added to the  $\vec{\kappa}_D$ -degree of  $D$ . Note that

$$\vec{0}\text{-deg} \begin{bmatrix} P^+ + P^- \\ I \end{bmatrix} = \vec{0}\text{-deg} \begin{bmatrix} P^+ \\ I \end{bmatrix}$$

because  $P^- = O_-(z^{-1})$ .

Hence, to find all matrix rational functions  $Z$  solving the GMPR problem, when  $M$  does not satisfy  $M = O_-(z^{\kappa_{N,i} - \kappa_{D,j} - 1})$  but  $\kappa_{N,i} \geq \kappa_{D,j} \quad \forall i, j$ , we have to find all  $D$  having minimal  $\vec{\kappa}_D$ -degree and all  $N$  such that  $ND^{-1} - M^- = O_-(z^{\Sigma})$ . If  $\Sigma \leq [\kappa_{N,i} - \kappa_{D,j} - 1]$  (elementwise), all solutions can be written as

$$Z^+ + ND^{-1} \quad \text{with} \quad Z^+ = M^+.$$

If the condition  $\Sigma \leq [\kappa_{N,i} - \kappa_{D,j} - 1]$  is not true for some of the elements of  $\Sigma$ , we also have to fill in the free parameters of  $Z^+$  such that

$$\vec{0}\text{-deg} \begin{bmatrix} z^{-\vec{\kappa}_N} Z^+ z^{\vec{\kappa}_D} \\ I \end{bmatrix} \text{ is minimal.}$$

We can do this by making the matrix

$$\begin{bmatrix} z^{-\vec{\kappa}_N} Z^+ z^{\vec{\kappa}_D} \\ I \end{bmatrix} \text{ column-reduced}$$

with the sum of the column degrees as small as possible. This can lead to certain conditions on the free parameters as in Example 17 of Section 8.

To make a polynomial matrix column reduced, we can use the following procedure. Consider the following elementary polynomial transformation matrices:

$E_{i,j} :=$  the unit matrix in which column  $i$  and column  $j$  are interchanged;

$E_{i,j}(q(z)) :=$  the unit matrix in which column  $j$  is replaced by column  $j$  plus  $q(z) \in \mathbf{F}[z]$  times column  $i$ ;

$E_i(k) :=$  the unit matrix where column  $i$  is multiplied by  $k \in \mathbf{F} \setminus \{0\}$ .

Suppose we have a polynomial  $p \times q$  matrix  $A(z)$  having full column rank. The coefficient of degree  $k$  of element  $a_{i,j}(z)$  is denoted by  $a_{i,j,k}$ . The degrees of the columns of  $A(z)$  are denoted by  $\alpha_1, \dots, \alpha_n$ .

To make this polynomial matrix column reduced, i.e., where the highest degree coefficients of the columns are linearly independent, we can use the

following algorithm:

ALGORITHM 7.1.

**While** not column reduced

1. Consider the set of linear equations

$$\begin{bmatrix} a_{1,1,\alpha_1} & \cdots & a_{1,q,\alpha_q} \\ \vdots & & \vdots \\ a_{p,1,\alpha_1} & \cdots & a_{p,q,\alpha_q} \end{bmatrix} \begin{bmatrix} c_1 \\ \vdots \\ c_q \end{bmatrix} = \begin{bmatrix} 0 \\ \vdots \\ 0 \end{bmatrix},$$

which always has a nontrivial solution  $c_i$ .

2. Define  $l := \max\{\alpha_i \mid c_i \neq 0\}$ .
3. Replace  $A$  by  $A \prod_{i=1, i \neq l}^q E_{i,l}(-c_i z^{\alpha_l - \alpha_i} / c_l)$ .

The idea of the algorithm is to make the highest degree coefficient of column  $l$  of  $A$  zero by subtracting shifted versions of the other columns. As long as the free parameters do not appear in the highest degree coefficients, Algorithm 7.1 can be run straightforwardly. Otherwise, it is sometimes possible to make the highest degree coefficients linearly dependent by imposing conditions on the free parameters.

## 8. EXAMPLES

EXAMPLE 16. Take  $\vec{\kappa}_N = [1, 0]^T$ ,  $\vec{\kappa}_D = [0, -1]^T$ ,  $\vec{\gamma} = [3, 4]^T$ ,

$$\begin{aligned} M(z) &= \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} z^2 + \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} z^1 + \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix} z^0 + \begin{bmatrix} 0 & 1 \\ 0 & -1 \end{bmatrix} z^{-1} \\ &+ \begin{bmatrix} 1 & * \\ 0 & -1 \end{bmatrix} z^{-2} + \begin{bmatrix} * & * \\ 2 & * \end{bmatrix} z^{-3} + \cdots \end{aligned}$$

The matrix  $[\kappa_{N,i} - \kappa_{D,j}]$  is equal to

$$[\kappa_{N,i} - \kappa_{D,j}] = \begin{bmatrix} 1 & 2 \\ 0 & 1 \end{bmatrix}.$$

Hence,  $M \neq O_-(z^{\kappa_{N,i} - \kappa_{D,j} - 1})$  but  $\kappa_{N,i} \geq \kappa_{D,j} \quad \forall i, j$ , and  $\Sigma = [-\gamma_i - \kappa_{D,j}] \leq [\kappa_{N,i} - \kappa_{D,j} - 1]$ . Therefore, the “polynomial” part  $Z^+$  is fixed:

$$Z^+ = \pi_{\kappa_{N,i} - \kappa_{D,j}}^+ M = \begin{bmatrix} z^2 & 0 \\ 1 & 0 \end{bmatrix}.$$

Using Algorithm 6.1, we get the following basis matrix connected to the interpolation problem  $ND^{-1} - M^- = O_-(z^\Sigma)$ :

$$\begin{bmatrix} 1 & -3z^2 - 3 & -1 & -z^2 - 2z - 1 \\ 0 & +2 & 0 & 0 \\ 0 & -z^2 & -1 & -z^2 \\ 0 & -2z & 0 & -2 \\ (3) & (2) & (1) & (2) \end{bmatrix} = \begin{bmatrix} \vec{b}_1 & \vec{b}_2 & \vec{b}_3 & \vec{b}_4 \\ (\beta_1) & (\beta_2) & (\beta_3) & (\beta_4) \end{bmatrix}.$$

Therefore any matrix rational function  $Z$  which solves the GMPR problem can be written as a RCPMFD  $Z = ND^{-1} + Z^+$  with

$$\begin{bmatrix} N \\ D \end{bmatrix} = [\vec{b}_1, \vec{b}_2, \vec{b}_3, \vec{b}_4] \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ az + b & cz + d \\ 0 & 1 \end{bmatrix}.$$

$Z$  has minimal  $\vec{\kappa}$ -McMillan degree equal to

$$\vec{0}\text{-deg} \begin{bmatrix} z^1 & 0 \\ 1 & 0 \\ 1 & 0 \\ 0 & 1 \end{bmatrix} + \vec{\kappa}_D\text{-deg } D = 1 + 4 = 5.$$

EXAMPLE 17. Take  $\vec{\kappa}_N = [1, 0]^T$ ,  $\vec{\kappa}_D = [0, -1]^T$ ,  $\Sigma = \begin{bmatrix} 2 & 3 \\ -2 & -1 \end{bmatrix}$ ,

$$\begin{aligned} M(z) &= \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} z^4 + \begin{bmatrix} 1 & * \\ 0 & 1 \end{bmatrix} z^3 + \begin{bmatrix} * & * \\ 1 & -1 \end{bmatrix} z^2 + \begin{bmatrix} * & * \\ 1 & 0 \end{bmatrix} z^1 \\ &+ \begin{bmatrix} * & * \\ 0 & 0 \end{bmatrix} z^0 + \begin{bmatrix} * & * \\ 1 & * \end{bmatrix} z^{-1} + \dots \end{aligned}$$

The matrix  $[\kappa_{N,i} - \kappa_{D,j}]$  is equal to

$$[\kappa_{N,i} - \kappa_{D,j}] = \begin{bmatrix} 1 & 2 \\ 0 & 1 \end{bmatrix}.$$

Hence,  $M \neq O_-(z^{\kappa_{N,i}-\kappa_{D,j}-1})$  and  $\Sigma = [-\gamma_i - \kappa_{D,j}] \not\leq [\kappa_{N,i} - \kappa_{D,j} - 1]$ , but  $\kappa_{N,i} \geq \kappa_{D,j} \forall i, j$ . Therefore, the "polynomial" part  $Z^+$  is not fixed:

$$Z^+ = \pi_{\kappa_{N,i}-\kappa_{D,j}}^+ M = \begin{bmatrix} z^3 + az^2 + bz & z^4 + cz^3 + dz^2 \\ z^2 + z & z^3 - z^2 \end{bmatrix}.$$

Hence,

$$\vec{0}\text{-deg} \begin{bmatrix} P^+ \\ I \end{bmatrix}$$

is equal to 2 when  $a - c = 2$ . Otherwise, it is equal to 3. Using Algorithm 6.1 to solve the GMPR problem for  $M^-$  with

$$\Sigma' = \begin{bmatrix} 0 & 1 \\ -2 & -1 \end{bmatrix},$$

we get the following basis matrix:

$$B = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & z & 1 & 0 \\ 0 & 0 & 0 & 1 \\ (0) & (1) & (1) & (1) \end{bmatrix} = \begin{bmatrix} \vec{b}_1 & \vec{b}_2 & \vec{b}_3 & \vec{b}_4 \\ (\beta_1) & (\beta_2) & (\beta_3) & (\beta_4) \end{bmatrix}.$$

Therefore any matrix rational function  $Z$  which solves the GMPR problem can be written as a RCPMFD  $Z = ND^{-1} + Z^+$  with  $a = c + 2$ ,  $b, c, d, e, f, g, h, i, j$  arbitrary, and

$$\begin{bmatrix} N \\ D \end{bmatrix} = \begin{bmatrix} \vec{b}_1, \vec{b}_2, \vec{b}_3, \vec{b}_4 \end{bmatrix} \begin{bmatrix} ez + f & gz + h \\ 1 & 0 \\ i & j \\ 0 & 1 \end{bmatrix}.$$

$Z$  has minimal  $\vec{\kappa}$ -McMillan degree equal to

$$2 + \vec{\kappa}_D\text{-deg } D = 2 + 2 = 4.$$

## 9. CONCLUSION

In this paper, we have shown that all solutions of the GMPR problem can be parametrized in a nice way

- (1) if  $M = O_-(z^{\kappa_{N,i} - \kappa_{D,j}} - 1)$  and
  - (2) if  $\Sigma$ , determining the order conditions, has the form  $\Sigma = [-\gamma_i - \kappa_{D,j}]$  and satisfies  $\Sigma \leq [\kappa_{N,i} - \kappa_{D,j} - 1]$  (elementwise),
- or

- (1) if  $\kappa_{N,i} \geq \kappa_{D,j}$ ,  $i = 1, 2, \dots, p$  and  $j = 1, 2, \dots, q$ , and
- (2) if  $\Sigma$  has the form  $\Sigma = [-\gamma_i - \kappa_{D,j}]$ .

If in the second case the free parameters start to influence the flow of Algorithm 7.1, it is possible that additional conditions have to be imposed on the free parameters to make the  $\vec{\kappa}$ -McMillan degree minimal.
